## **Cheat Sheet: Python Data Structures Part-2**

## **Dictionaries**

Package/Method	Description	Code Example
		Example:
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	1. 1 2. 2
		<pre>1. dict_name = {} #Creates an empty dictionary 2. person = { "name": "John", "age": 30, "city": "New York"}</pre>
Accessing Values	You can access the values in a dictionary using their corresponding keys.	Copied!
		Syntax:
		1. 1
		1. Value = dict_name["key_name"]
		Copied!
		Example:
		1. 1 2. 2
		<pre>1. name = person["name"] 2. age = person["age"]</pre>
		Copied!
Add or modify	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	Syntax:
		<pre>1. 1 1. dict_name[key] = value</pre>
		Copied!
		Example:
		1. 1 2. 2
		<ol> <li>person["Country"] = "USA" # A new entry will be created.</li> <li>person["city"] = "Chicago" # Update the existing value for the same key</li> </ol>
del	Removes the specified key-value pair from the dictionary. Raises a KeyError if the key does not exist.	Copied!
		Syntax:
		<ol> <li>1. 1</li> <li>1. del dict_name[key]</li> </ol>
		Copied!
		1. 1
		1. del person["Country"]
		Copied!
		Syntax:
		1. 1
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating keyvalue pairs.	<pre>1. dict_name.update({key: value})</pre>
		Copied!
		Example:
		1. 1
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	1. person.update({"Profession": "Doctor"})
		Copied! Syntax:
		1. 1
		<pre>1. dict_name.clear()</pre>
		Copied!

```
1. 1
                                                                         1. grades.clear()
                                                                       Copied!
                                                                      Example:
                                                                         1. 1
                  You can check for the existence of a key in a dictionary
key existence
                  using the in keyword
                                                                         1. if "name" in person:
                                                                                 print("Name exists in the dictionary.")
                                                                       Copied!
                                                                      Syntax:
                                                                         1. 1
                                                                         1. new_dict = dict_name.copy()
                                                                       Copied!
                  Creates a shallow copy of the dictionary. The new
                  dictionary contains the same key-value pairs as the
copy()
                                                                      Example:
                  original, but they remain distinct objects in memory.
                                                                         1. 1
                                                                         1. new_person = person.copy()
                                                                         2. new_person = dict(person) # another way to create a copy of dictionary
                                                                       Copied!
                                                                      Syntax:
                                                                         1. keys_list = list(dict_name.keys())
                  Retrieves all keys from the dictionary and converts
                                                                        Copied!
keys()
                  them into a list. Useful for iterating or processing keys
                                                                      Example:
                  using list methods.
                                                                         1. person_keys = list(person.keys())
                                                                        Copied!
                                                                      Syntax:
                                                                         1. 1
                                                                         1. values_list = list(dict_name.values())
                  Extracts all values from the dictionary and converts
                                                                       Copied!
                  them into a list. This list can be used for further
values()
                  processing or analysis.
                                                                      Example:
                                                                         1. person_values = list(person.values())
                                                                        Copied!
                                                                      Syntax:
                                                                         1. 1
                                                                         1. items_list = list(dict_name.items())
                  Retrieves all key-value pairs as tuples and converts
                                                                       Copied!
items()
                  them into a list of tuples. Each tuple consists of a key
                  and its corresponding value.
                                                                      Example:
                                                                         1. 1
                                                                         1. info = list(person.items())
                                                                       Copied!
Sets
```

Code Example

1. set\_name.add(element)

Copied!

Description

removed, as sets only store unique values.

Elements can be added to a set using the `add()` method. Duplicates are automatically Syntax:

Package/Method

add()

Example:

```
Example:
                                                                                                           1. 1
                                                                                                           1. fruits.add("mango")
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. set_name.clear()
                                                                                                         Copied!
                  The `clear()` method removes all elements from the set, resulting in an empty set. It
clear()
                  updates the set in-place.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. fruits.clear()
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. new_set = set_name.copy()
                                                                                                         Copied!
                  The `copy()` method creates a shallow copy of the set. Any modifications to the copy
copy()
                  won't affect the original set.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. new_fruits = fruits.copy()
                                                                                                         Copied!
                                                                                                        Example:
                                                                                                           1. 1
                  A set is an unordered collection of unique elements. Sets are enclosed in curly braces
Defining Sets
                  `{}`. They are useful for storing distinct values and performing set operations.
                                                                                                           1. empty_set = set() #Creating an Empty
2. Set fruits = {"apple", "banana", "orange"}
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. set name.discard(element)
                                                                                                         Copied!
                  Use the 'discard()' method to remove a specific element from the set. Ignores if the
discard()
                  element is not found.
                                                                                                        Example:
                                                                                                           1. fruits.discard("apple")
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. is_subset = set1.issubset(set2)
                                                                                                         Copied!
                  The `issubset()` method checks if the current set is a subset of another set. It returns
issubset()
                  True if all elements of the current set are present in the other set, otherwise False.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. is_subset = fruits.issubset(colors)
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                        is_superset = set1.issuperset(set2)
                  The `issuperset()` method checks if the current set is a superset of another set. It
                                                                                                        Example:
issuperset()
                  returns True if all elements of the other set are present in the current set, otherwise
                  False.
                                                                                                           1. is_superset = colors.issuperset(fruits)
                                                                                                         Copied!
pop()
                  The 'pop()' method removes and returns an arbitrary element from the set. It raises a
                                                                                                        Syntax:
                  `KeyError` if the set is empty. Use this method to remove elements when the order
                  doesn't matter.
                                                                                                           1. removed_element = set_name.pop()
```

1. 1 1. removed\_fruit = fruits.pop() Copied! Syntax: 1. 1 1. set\_name.remove(element) Copied! Use the `remove()` method to remove a specific element from the set. Raises a remove() `KeyError` if the element is not found. Example: 1. 1 1. fruits.remove("banana") Copied! Syntax: 2. 2 3. 3 4. 4 1. union\_set = set1.union(set2) 2. intersection\_set = set1.intersection(set2)
3. difference\_set = set1.difference(set2)
4. sym\_diff\_set = set1.symmetric\_difference(set2) Copied! Perform various operations on sets: 'union', 'intersection', 'difference', 'symmetric Set Operations difference`. Example: 1. 1 2. 2 3. 3 4. 4 1. combined = fruits.union(colors) common = fruits.intersection(colors)
 unique\_to\_fruits = fruits.difference(colors)
 sym\_diff = fruits.symmetric\_difference(colors) Copied! Syntax: 1. 1 1. set\_name.update(iterable) Copied! The 'update()' method adds elements from another iterable into the set. It maintains update() the uniqueness of elements. Example: 1. 1 1. fruits.update(["kiwi", "grape"]) Copied!

Copied!
