## **Python Data Structures Cheat Sheet**

## List

Package/Method	Description	Code Example
append()	The `append()` method is used to add an element to the end of a list.	<pre>Syntax: 1. 1 1. list_name.append(element)  Copied!  Example: 1. 1 2. 2 1. fruits = ["apple", "banana", "orange"] 2. fruits.append("mango") print(fruits)  Copied!  Example 1:</pre>
copy()	The `copy()` method is used to create a shallow copy of a list.	1. 1 2. 2 3. 3  1. my_list = [1, 2, 3, 4, 5] 2. new_list = my_list.copy() print(new_list) 3. # Output: [1, 2, 3, 4, 5]  Copied!
count()	The `count()` method is used to count the number of occurrences of a specific element in a list in Python.	Example:  1. 1 2. 2 3. 3  1. my_list = [1, 2, 2, 3, 4, 2, 5, 2] 2. count = my_list.count(2) print(count) 3. # Output: 4
Creating a list	A list is a built-in data type that represents an ordered and mutable collection of elements. Lists are enclosed in square brackets [] and elements are separated by commas.	Copied!  Example:  1. 1  1. fruits = ["apple", "banana", "orange", "mango"]  Copied!  Example:
del	The `del` statement is used to remove an element from list. `del` statement removes the element at the specified index.	1. 1 2. 2
extend()	The `extend()` method is used to add multiple elements to a list. It takes an iterable (such as another list, tuple, or string) and appends each element of the iterable to the original list.	<pre>1. 1 1. list_name.extend(iterable)  Copied!  Example:  1. 1 2. 2 3. 3 4. 4  1. fruits = ["apple", "banana", "orange"] 2. more_fruits = ["mango", "grape"] 3. fruits.extend(more_fruits) 4. print(fruits)</pre>
Indexing	Indexing in a list allows you to access individual elements by their position. In Python, indexing starts from 0 for the first element and goes up to `length_of_list - 1`.	Copied!  Example:  1. 1 2. 2 3. 3

```
5.5
                                                                                              1. my_list = [10, 20, 30, 40, 50]
                                                                                             1. my_list = [10, 20, 30, 40, 30]
2. print(my_list[0])
3. # Output: 10 (accessing the first element)
4. print(my_list[-1])
5. # Output: 50 (accessing the last element using negative indexing)
                                                                                           Copied!
                                                                                          Syntax:
                                                                                              1. 1

    list_name.insert(index, element)

                                                                                           Copied!
                                                                                          Example:
                        The `insert()` method is used to insert an
insert()
                        element.
                                                                                              1. 1
2. 2
3. 3
                                                                                             1. my_list = [1, 2, 3, 4, 5]
2. my_list.insert(2, 6)
                                                                                              3. print(my_list)
                                                                                           Copied!
                                                                                          Example:
                                                                                              2. 2 3. 3
                                                                                              4. 4
                        You can use indexing to modify or assign new
Modifying a list
                        values to specific elements in the list.
                                                                                             1. my_list = [10, 20, 30, 40, 50]
2. my_list[1] = 25 # Modifying the second element
3. print(my_list)
4. # Output: [10, 25, 30, 40, 50]
                                                                                           Copied!
                                                                                          Example 1:
                                                                                              1. 1
                                                                                              2. 2
3. 3
                                                                                              4. 4
5. 5
6. 6
                                                                                             1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop(2) # Removes and returns the element at index 2
3. print(removed_element)
4. # Outputs 20.
                                                                                              4. # Output: 30
                                                                                              6. print(my_list)
7. # Output: [10, 20, 40, 50]
                        `pop()` method is another way to remove an
                        element from a list in Python. It removes and
                                                                                           Copied!
                        returns the element at the specified index. If you
pop()
                        don't provide an index to the `pop()` method, it
                                                                                          Example 2:
                        will remove and return the last element of the list
                        by default
                                                                                              1. 1
2. 2
3. 3
4. 4
                                                                                              5.5
                                                                                              6. 6
7. 7
                                                                                             1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop() # Removes and returns the last element
3. print(removed_element)
4. # Output: 50
                                                                                              6. print(my_list)
7. # Output: [10, 20, 30, 40]
                                                                                           Copied!
                                                                                          Example:
                                                                                              1. 1
2. 2
3. 3
                        To remove an element from a list. The
                        `remove()` method removes the first occurrence
remove()
                                                                                             1. my_list = [10, 20, 30, 40, 50]
2. my_list.remove(30) # Removes the element 30
3. print(my_list)
4. # Output: [10, 20, 40, 50]
                        of the specified value.
                                                                                           Copied!
```

4. 4

```
1. 1
2. 2
                                                                                   3.3
                      The `reverse()` method is used to reverse the
reverse()
                      order of elements in a list
                                                                                   1. my_list = [1, 2, 3, 4, 5]
2. my_list.reverse() print(my_list)
3. # Output: [5, 4, 3, 2, 1]
                                                                                 Copied!
                                                                                Syntax:
                                                                                   1. 1
                                                                                   1. list_name[start:end:step]
                                                                                Copied!
                                                                                Example:
                                                                                   1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7
8. 8
9. 9
                      You can use slicing to access a range of elements
Slicing
                      from a list.
                                                                                  10. 10
                                                                                  11. 11
                                                                                 12. 12
                                                                                   1. my_list = [1, 2, 3, 4, 5]
2. print(my_list[1:4])
3. # Output: [2, 3, 4] (elements from index 1 to 3)
                                                                                   4.
                                                                                   5. print(my_list[:3])
6. # Output: [1, 2, 3] (elements from the beginning up to index 2)
                                                                                   %. print(my_list[2:])
9. # Output: [3, 4, 5] (elements from index 2 to the end)
                                                                                 10.
                                                                                 11. print(my_list[::2])
12. # Output: [1, 3, 5] (every second element)
                                                                                 Copied!
                                                                                Example 1:
                                                                                   1. 1
2. 2
                                                                                   3. 3
4. 4
                                                                                   1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort()
                                                                                   3. print(my_list)
                                                                                   4. # Output: [1, 2, 5, 8, 9]
                      The `sort()` method is used to sort the elements
                                                                                 Copied!
                      of a list in ascending order. If you want to sort
sort()
                      the list in descending order, you can pass the
                                                                                Example 2:
                      `reverse=True` argument to the `sort()` method.
                                                                                   1. 1
                                                                                   2. 2
3. 3
                                                                                   1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort(reverse=True)
3. print(my_list)
4. # Output: [9, 8, 5, 2, 1]
                                                                                 Copied!
Dictionary
 Package/Method
                                                 Description
                                                                                                                                       Code Example
Accessing Values You can access the values in a dictionary using their
                                                                                          Syntax:
                       corresponding 'keys'.
                                                                                             1. 1
                                                                                             1. Value = dict_name["key_name"]
                                                                                          Copied!
                                                                                          Example:
                                                                                            1. 1
2. 2
                                                                                             1. name = person["name"]
                                                                                             2. age = person["age"]
```

Example 1:

```
Copied!
                                                                             Syntax:
                                                                                1. 1
                                                                                1. dict_name[key] = value
                                                                              Copied!
                    Inserts a new key-value pair into the dictionary. If the
Add or modify
                    key already exists, the value will be updated; otherwise, Example:
                   a new entry is created.
                                                                                1. 1
2. 2

    person["Country"] = "USA" # A new entry will be created.
    person["city"] = "Chicago" # Update the existing value for the same key

                                                                              Copied!
                                                                             Syntax:
                                                                                1. 1
                                                                                1. dict_name.clear()
                   The 'clear()' method empties the dictionary, removing
                                                                              Copied!
                   all key-value pairs within it. After this operation, the
clear()
                                                                             Example:
                    dictionary is still accessible and can be used further.
                                                                                1. 1
                                                                                1. grades.clear()
                                                                              Copied!
                                                                             Syntax:
                                                                                1. 1
                                                                                1. new_dict = dict_name.copy()
                                                                              Copied!
                   Creates a shallow copy of the dictionary. The new
copy()
                    dictionary contains the same key-value pairs as the
                                                                             Example:
                    original, but they remain distinct objects in memory.
                                                                                1. 1
                                                                                2. 2
                                                                                1. new_person = person.copy()
                                                                                2. new_person = dict(person) # another way to create a copy of dictionary
                                                                              Copied!
                                                                             Example:
                                                                                1. 1
                    A dictionary is a built-in data type that represents a
Creating a
                   collection of key-value pairs. Dictionaries are enclosed
Dictionary
                                                                                1. dict_name = {} #Creates an empty dictionary
2. person = { "name": "John", "age": 30, "city": "New York"}
                    in curly braces `{}`.
                                                                              Copied!
                                                                             Syntax:
                                                                                1. 1

    del dict_name[key]

                                                                               Copied!
                    Removes the specified key-value pair from the
del
                   dictionary. Raises a `KeyError` if the key does not exist. Example:
                                                                                1. 1
                                                                                1. del person["Country"]
                                                                              Copied!
                                                                             Syntax:
                                                                                1. 1
                                                                                1. items_list = list(dict_name.items())
                    Retrieves all key-value pairs as tuples and converts them Copied!
items()
                    into a list of tuples. Each tuple consists of a key and its
                                                                             Example:
                   corresponding value.
                                                                                1. 1
                                                                                1. info = list(person.items())
                    You can check for the existence of a key in a dictionary Example:
key existence
                    using the 'in' keyword
                                                                                1. 1
```

```
1. if "name" in person:
                                                                                   print("Name exists in the dictionary.")
                                                                         Copied!
                                                                        Syntax:
                                                                          1. 1
                                                                          1. keys_list = list(dict_name.keys())
                  Retrieves all keys from the dictionary and converts them Copied!
keys()
                  into a list. Useful for iterating or processing keys using
                                                                        Example:
                  list methods.
                                                                          1. 1
                                                                          1. person_keys = list(person.keys())
                                                                        Copied!
                                                                        Syntax:
                                                                          1. 1
                                                                          1. dict_name.update({key: value})
                                                                        Copied!
                  The 'update()' method merges the provided dictionary
update()
                  into the existing dictionary, adding or updating key-
                                                                        Example:
                   value pairs.
                                                                          1. 1
                                                                          1. person.update({"Profession": "Doctor"})
                                                                         Copied!
                                                                        Syntax:
                                                                          1. 1
                                                                          1. values_list = list(dict_name.values())
                                                                        Copied!
                   Extracts all values from the dictionary and converts
                  them into a list. This list can be used for further
values()
                                                                        Example:
                  processing or analysis.
                                                                          1. 1
                                                                          1. person_values = list(person.values())
                                                                         Copied!

Package/Method
                                                     Description
                                                                                                                           Code Example
                                                                                                    Syntax:
                                                                                                       1. 1
                                                                                                       1. set_name.add(element)
                                                                                                     Copied!
                 Elements can be added to a set using the `add()` method. Duplicates are automatically
add()
                 removed, as sets only store unique values.
                                                                                                    Example:
                                                                                                       1. 1
                                                                                                       1. fruits.add("mango")
                                                                                                     Copied!
                                                                                                    Syntax:
                                                                                                       1. 1
                                                                                                       1. set name.clear()
                                                                                                     Copied!
                 The `clear()` method removes all elements from the set, resulting in an empty set. It
clear()
                 updates the set in-place.
                                                                                                    Example:
                                                                                                       1. 1
                                                                                                       1. fruits.clear()
                                                                                                      Copied!
                 The `copy()` method creates a shallow copy of the set. Any modifications to the copy
                                                                                                    Syntax:
copy()
                 won't affect the original set.
                                                                                                       1. new_set = set_name.copy()
```

Copied!

2. 2

```
1. 1
                                                                                                           1. new_fruits = fruits.copy()
                                                                                                         Copied!
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           2. 2
                  A set is an unordered collection of unique elements. Sets are enclosed in curly braces
Defining Sets
                  `{}`. They are useful for storing distinct values and performing set operations.
                                                                                                           1. empty_set = set() #Creating an Empty Set
2. fruits = {"apple", "banana", "orange"}
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. set_name.discard(element)
                                                                                                         Copied!
                  Use the 'discard()' method to remove a specific element from the set. Ignores if the
discard()
                  element is not found.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. fruits.discard("apple")
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. is_subset = set1.issubset(set2)
                                                                                                         Copied!
                  The `issubset()` method checks if the current set is a subset of another set. It returns
issubset()
                  True if all elements of the current set are present in the other set, otherwise False.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. is_subset = fruits.issubset(colors)
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. is_superset = set1.issuperset(set2)
                                                                                                          Copied!
                  The `issuperset()` method checks if the current set is a superset of another set. It returns
issuperset()
                  True if all elements of the other set are present in the current set, otherwise False.
                                                                                                        Example:
                                                                                                           1. is_superset = colors.issuperset(fruits)
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. removed_element = set_name.pop()
                                                                                                         Copied!
                  The 'pop()' method removes and returns an arbitrary element from the set. It raises a
                  `KeyError` if the set is empty. Use this method to remove elements when the order
pop()
                                                                                                        Example:
                  doesn't matter.
                                                                                                           1. 1
                                                                                                           1. removed_fruit = fruits.pop()
                                                                                                         Copied!
                                                                                                        Syntax:
                                                                                                           1. 1
                                                                                                           1. set_name.remove(element)
                                                                                                         Copied!
                  Use the `remove()` method to remove a specific element from the set. Raises a
remove()
                  `KeyError` if the element is not found.
                                                                                                        Example:
                                                                                                           1. 1
                                                                                                           1. fruits.remove("banana")
                                                                                                         Copied!
```

Example:

```
2. 2
3. 3
4. 4
                                                                                                                                       1. union_set = set1.union(set2)
                                                                                                                                       2. intersection_set = set1.intersection(set2)
